# Notes on measure theory and topology

# Danny Nygård Hansen

#### 23rd October 2021

# 1 • Introduction

These notes are meant to serve two purposes: Firstly to give an account of (some of) the similarities between topological spaces and measurable spaces. Any student of topology and measure theory have noticed that while  $\sigma$ -algebras generally do not behave as nicely as topologies, we are able to perform many of the same constructions on both structures: Structure-preserving maps (countinuous and measurable maps, respectively) are defined the same way, maps induce topologies and  $\sigma$ -algebras in the same way, there are subspaces, products, quotients, and so on.

If we fix a set X, both the set of topologies and the set of  $\sigma$ -algebras on X are complete lattices when ordered by inclusion. I am not aware that such a lattice of structures on a set has a commonly used name, so I have simply called them *structures* in these notes.

Secondly we wish to explore how a topological and measure-theoretical structure on a single set interact.

#### 1.1. Notation

We generally use notation that is standard in topology, measure theory and category theory. The following may or may not be familiar to the reader:

Given a set X we denote its power set by  $2^X$ . If  $f: X \to Y$  is a set function,  $\mathcal{E} \subseteq 2^X$  and  $\mathcal{F} \subseteq 2^Y$ , we write

$$f(\mathcal{E}) = \{ f(A) \mid A \in \mathcal{E} \} \quad \text{and} \quad f^{-1}(\mathcal{F}) = \{ f^{-1}(B) \mid B \in \mathcal{F} \}.$$

For a set X and a family  $\mathcal{D} \subseteq 2^X$  of subsets, we write  $\sigma(\mathcal{D})$  for the  $\sigma$ -algebra on X generated by  $\mathcal{D}$ , i.e. the smallest  $\sigma$ -algebra containing  $\mathcal{D}$ . We do not use any special notation for a topology generated by a family of sets.

If *X* is a topological space, we denote the Borel  $\sigma$ -algebra on *X* by  $\mathcal{B}(X)$ .

2. Structured sets 2

# 2 • Structured sets

# 2.1. Definitions and basic properties

Let  $\mathfrak{S}$  be a map from sets to sets such that  $\mathfrak{S}_X := \mathfrak{S}(X)$  is a collection of subsets of  $2^X$ , and such that for all sets X and Y and maps  $f: X \to Y$ ,

- (1)  $\mathfrak{S}_X$  is partially ordered by set inclusion,
- (2)  $\mathfrak{S}_X$  is a complete lattice with minimum  $\{\emptyset, X\}$  and maximum  $2^X$ ,
- (3) if  $\mathcal{F} \in \mathfrak{S}_Y$ , then  $f^{-1}(\mathcal{F}) \in \mathfrak{S}_X$ , and
- (4) if  $\mathcal{E} \in \mathfrak{S}_X$ , then

$$\{B \subseteq Y \mid f^{-1}(B) \in \mathcal{E}\} \in \mathfrak{S}_Y.$$

We will call such a map  $\mathfrak{S}$  a *structure functor*, and it is indeed a functor as we will see in Subsection 2.4.

If X is a set, then a  $\mathcal{E} \in \mathfrak{S}_X$  is called a  $\mathfrak{S}$ -structure on X, and we will call the pair  $(X,\mathcal{E})$  a  $\mathfrak{S}$ -structured set. We refer to  $\mathfrak{S}_X$  as the *lattice of*  $\mathfrak{S}$ -structures on X. The minimal structure  $\{\emptyset,X\}$  is called the *trivial structure*, and the maximal structure  $2^X$  is called the *discrete structure* on X.

Fix a structure functor  $\mathfrak{S}$ . If  $(X, \mathcal{E})$  and  $(Y, \mathcal{F})$  are structured sets, a homomorphism from X to Y is a map  $f: X \to Y$  such that  $f^{-1}(\mathcal{F}) \subseteq \mathcal{E}$ . Clearly the composition of two homomorphisms is again a homomorphism, so the collection of structured sets and homomorphisms form a (locally small) category. Let us denote this category by  $\mathbf{Str}_{\mathfrak{S}}$ .

The structure  $f^{-1}(\mathcal{F})$  in Item (3) is called the *pullback* of  $\mathcal{F}$  by f and is denoted  $f^*(\mathcal{F})$ . Similarly, the structure  $\{B \subseteq Y \mid f^{-1}(B) \in \mathcal{E}\}$  in Item (4) is called the *pushforward* of  $\mathcal{E}$  by f and is denoted  $f_*(\mathcal{E})$ . The pullback and pushforward by f is defined for all set functions f, not just homomorphisms.

EXAMPLE 2.1. Let  $\mathfrak{S}$  denote the map that associates to a set its lattice of topologies. The first two conditions above are obviously satisfied, and the latter two are easily proved. Thus  $\mathbf{Str}_{\mathfrak{S}}$  is just the category  $\mathbf{Top}$  of topological spaces. Similarly, if  $\mathfrak{S}$  maps a set to its lattice of  $\sigma$ -algebras, then  $\mathbf{Str}_{\mathfrak{S}}$  is the category  $\mathbf{Mble}$  of measurable spaces.

In the sequel we fix a structure functor  $\mathfrak{S}$ .

#### LEMMA 2.2

Let X be a set. If  $\mathcal{D} \subseteq 2^X$ , then there is a smallest element  $\langle \mathcal{D} \rangle \in \mathfrak{S}_X$  with  $\mathcal{D} \subseteq \langle \mathcal{D} \rangle$ .

PROOF. Let  $\Sigma(\mathcal{D}) = \{ \mathcal{E} \in \mathfrak{S}_X \mid \mathcal{D} \subseteq \mathcal{E} \}$ . Since  $\mathfrak{S}_X$  is a complete lattice, we can put

$$\langle \mathcal{D} \rangle = \bigwedge_{\mathcal{E} \in \Sigma(\mathcal{D})} \mathcal{E} \in \mathfrak{S}_X.$$

If  $\langle \mathcal{D} \rangle = \mathcal{E}$ , then we say that  $\mathcal{D}$  generates or is a generating set for  $\mathcal{E}$ . It is easy to see that we may characterise joins as a particular generated structure, namely

$$\bigvee_{\alpha \in A} \mathcal{E}_{\alpha} = \left\langle \bigcup_{\alpha \in A} \mathcal{E}_{\alpha} \right\rangle. \tag{2.1}$$

# PROPOSITION 2.3

Let  $(X, \mathcal{E})$  and  $(Y, \mathcal{F})$  be structured sets, and let  $f: X \to Y$  be any map. For any  $\mathcal{D} \subseteq 2^Y$  we have

$$f^{-1}(\langle \mathcal{D} \rangle) = \langle f^{-1}(\mathcal{D}) \rangle.$$

In particular, if  $\mathcal{F} = \langle \mathcal{D} \rangle$ , then f is a homomorphism if and only if  $f^{-1}(\mathcal{D}) \subseteq \mathcal{E}$ .

In topology, this proposition is trivial since every element in  $\langle \mathcal{D} \rangle$  is a union of finite intersections of elements in  $\mathcal{D}$ . The proof below is identical to the one given in measure theory.

**PROOF.** First notice that  $f^{-1}(\mathcal{D}) \subseteq f^{-1}(\langle \mathcal{D} \rangle)$ , which implies that

$$\langle f^{-1}(\mathcal{D}) \rangle \subseteq f^{-1}(\langle \mathcal{D} \rangle).$$

For the second inclusion, notice that

$$\mathcal{A} = \left\{ B \subseteq Y \mid f^{-1}(B) \in \left\langle f^{-1}(\mathcal{D}) \right\rangle \right\}$$

is a set structure in *Y*. Since clearly  $\mathcal{D} \subseteq \mathcal{A}$ , we also have  $\langle \mathcal{D} \rangle \subseteq \mathcal{A}$ , which proves the second inclusion.

#### 2.2. Initial structures

### **DEFINITION 2.4:** *Initial structures*

Let  $(f_{\alpha})_{\alpha \in A}$  be a collection of maps from a set X to structured sets  $(X_{\alpha}, \mathcal{E}_{\alpha})$ . The *initial structure*  $\mathcal{E}$  on X induced by  $(f_{\alpha})$  is the smallest structure on X that makes all  $f_{\alpha}$  homomorphisms. That is,

$$\mathcal{E} = \bigvee_{\alpha \in A} f_{\alpha}^{*}(\mathcal{E}_{\alpha}) = \left\langle \bigcup_{\alpha \in A} f_{\alpha}^{-1}(\mathcal{E}_{\alpha}) \right\rangle.$$

REMARK 2.5. If  $\mathcal{D}_{\alpha}$  is a generating set for  $\mathcal{E}_{\alpha}$  for all  $\alpha \in A$ , then we may replace  $\mathcal{E}_{\alpha}$  on the right-hand side above with  $\mathcal{D}_{\alpha}$ . This follows immediately from the second part of Proposition 2.3, since the structure  $\left\langle \bigcup_{\alpha \in A} f_{\alpha}^{-1}(\mathcal{D}_{\alpha}) \right\rangle$  makes all  $f_{\alpha}$  into homomorphisms.

Note that  $\bigvee_{\alpha \in A} f_{\alpha}^*(\mathcal{D}_{\alpha})$  doesn't generally make sense, since  $\mathcal{D}_{\alpha}$  is not necessarily a structure on  $X_{\alpha}$ .

### THEOREM 2.6: Characteristic property of initial structures

Let  $(X,\mathcal{E})$  be a structured set equipped with the initial structure induced by maps  $f_{\alpha} \colon X \to X_{\alpha}$ ,  $\alpha \in A$ . If  $(Y,\mathcal{F})$  is a structured set, then  $f \colon Y \to X$  is a homomorphism if and only if  $f_{\alpha} \circ f$  is a homomorphism for all  $\alpha \in A$ :

$$\begin{array}{ccc}
X & \xrightarrow{f_{\alpha}} X_{\alpha} \\
f \uparrow & \xrightarrow{f_{\alpha} \circ f}
\end{array}$$

*Furthermore, the initial structure on X is unique with this property.* 

**PROOF.** If f is a homomorphism, then clearly the  $f_{\alpha} \circ f$  are all homomorphisms.

Conversely, assume that all compositions  $f_{\alpha} \circ f$  are homomorphisms. It suffices to show that  $f^{-1}(B) \in \mathcal{F}$  for all B from a generating set for  $\mathcal{E}$ , so let  $B = f_{\alpha}^{-1}(C)$  for some  $\alpha \in A$  and  $C \in \mathcal{E}_{\alpha}$ . It follows that

$$f^{-1}(B) = f^{-1}(f_\alpha^{-1}(C)) = (f_\alpha \circ f)^{-1}(C) \in \mathcal{F}$$

as desired.

We now show that the characteristic property uniquely determines a structure on X. First notice that the commutative diagram

$$X \xrightarrow{f_{\alpha}} X_{\alpha}$$

$$id_{X} \uparrow f_{\alpha}$$

$$X$$

shows that  $f_{\alpha}$  is a homomorphism, and that this only depends on  $\mathcal{E}$  having the characteristic property above, and not on the concrete definition of  $\mathcal{E}$ .

Now assume that  $\mathcal{E}'$  is a structure on X with the characteristic property. Consider the commutative diagram

$$(X, \mathcal{E}') \xrightarrow{f_{\alpha}'} X_{\alpha}$$

$$id_{X} \uparrow \qquad \qquad f_{\alpha}$$

$$(X, \mathcal{E})$$

where a prime denotes that the domain of a map is  $(X, \mathcal{E}')$  but is as a set function the same as its unprimed counterpart. The  $f_{\alpha}$  are homomorphisms, so by the characteristic property applied to  $\mathcal{E}'$  we get that  $\mathrm{id}_X$  is a homomorphism.

Finally consider the analogous diagram with primes interchanged:

$$(X,\mathcal{E}) \xrightarrow{f_{\alpha}} X_{\alpha}$$

$$id'_{X} \uparrow \qquad \qquad f'_{\alpha}$$

$$(X,\mathcal{E}')$$

The  $f'_{\alpha}$  are homomorphisms as we showed above, since  $\mathcal{E}'$  by assumption satisfies the characteristic property. Applying the characteristic property to  $\mathcal{E}$  then shows that  $\mathrm{id}'_X$  is a homomorphism. Thus  $(X,\mathcal{E})$  and  $(X,\mathcal{E}')$  are isomorphic through the identity, hence  $\mathcal{E} = \mathcal{E}'$ .

#### **EXAMPLE 2.7: Subsets.**

Let  $(X, \mathcal{E})$  be a structured set, and let  $S \subseteq X$ . The inclusion map  $\iota_S \colon S \to X$  then induces an initial structure on S, namely the pullback  $\iota_S^*(\mathcal{E})$ . We denote this subset structure by  $\mathcal{E}_S$ , and unless otherwise noted subsets of structured sets always carry this structure. By the characteristic property of initial structures, a map  $f \colon Y \to S$  from a structured set is a homomorphism if and only if  $\iota_S \circ f$  is a homomorphism.

On the other hand, if  $f: Y \to X$  is a map with  $f(Y) \subseteq S$ , then the map  $\tilde{f}: Y \to S$  given by  $\tilde{f}(y) = f(y)$  for all  $y \in Y$  is a homomorphism if and only if  $f = \iota_S \circ \tilde{f}$  is a homomorphism. In other words, whether a map is a homomorphism or not does not depend on the codomain if we agree to equip subsets with the structure induced by their inclusion maps.

If S = f(Y) and  $\tilde{f}: Y \to f(Y)$  is an isomorphism, then we call f an *embedding*.

#### **EXAMPLE 2.8: Products.**

Let  $(X_{\alpha}, \mathcal{E}_{\alpha})_{\alpha \in A}$  be a collection of structured sets, let  $X = \prod_{\alpha \in A} X_{\alpha}$  be the Cartesian product of the sets  $X_{\alpha}$ , and denote the associated projections by  $\pi_{\alpha} \colon X \to X_{\alpha}$ . We define a product structure

$$\mathcal{E} = \bigotimes_{\alpha \in A} \mathcal{E}_{\alpha}$$

as the initial structure on X induced by the projection maps. Since X is a product of the  $X_{\alpha}$  in the category of sets, the characteristic property of initial structures implies that  $(X, \mathcal{E})$  is a product of the structured sets  $(X_{\alpha}, \mathcal{E}_{\alpha})$ .

#### PROPOSITION 2.9: Composition of initial structures

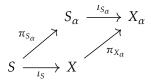

For  $\alpha \in A$  and  $\lambda \in \Lambda_{\alpha}$ , let  $X_{\alpha}$  and  $Y_{\alpha\lambda}$  be structured sets such that each  $X_{\alpha}$  carry the initial structure induced by maps  $g_{\alpha\lambda} \colon X_{\alpha} \to Y_{\alpha\lambda}$  for  $\lambda \in \Lambda_{\alpha}$ . Let X be a set, and consider maps  $f_{\alpha} \colon X \to X_{\alpha}$ .

Let  $\mathcal{E}_1$  be the initial structure on X induced by the maps  $f_{\alpha}$ , and let  $\mathcal{E}_2$  be the structure induced by the compositions  $g_{\alpha\lambda} \circ f_{\alpha}$ . Then  $\mathcal{E}_1 = \mathcal{E}_2$ .

PROOF. By the characteristic property of initial structures, the  $f_{\alpha}$  are homomorphisms if and only if all the  $g_{\alpha\lambda} \circ f_{\alpha}$  are homomorphisms. If X has the structure  $\mathcal{E}_1$ , then we must have  $\mathcal{E}_2 \subseteq \mathcal{E}_1$ , since these compositions  $g_{\alpha\lambda} \circ f_{\alpha}$  are homomorphisms. Conversely, if X carries the structure  $\mathcal{E}_2$ , then the  $f_{\alpha}$  are homomorphisms, and so  $\mathcal{E}_1 \subseteq \mathcal{E}_2$ .

#### EXAMPLE 2.10: Subspace and product structures.

Let  $(X_{\alpha})_{\alpha \in A}$  be a family of structured sets, and let  $S_{\alpha} \subseteq X_{\alpha}$  be subsets. Then we may equip the product  $S = \prod_{\alpha \in A} S_{\alpha}$  by first equipping  $X = \prod_{\alpha \in A} X_{\alpha}$  with the product structure, and then induce the subset structure on S. In the opposite order we may first equip each  $S_{\alpha}$  with the subset structure, and then induce the product structure. These in fact give the same structure since the diagram

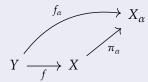

commutes.

### EXAMPLE 2.11: The weak\*-topology.

Let X be a topological vector space over the field  $\mathbb{F}$  with topological dual  $X^*$ , and for  $x \in X$  let  $\operatorname{ev}_x \colon X^* \to \mathbb{F}$  be the evaluation map  $\operatorname{ev}_x(\varphi) = \varphi(x)$  for  $\varphi \in X^*$ . Since  $X^*$  is a subset of  $\mathbb{F}^X$ , it naturally carries the subspace topology. The product topology on  $\mathbb{F}^X$  is induced by the projection maps  $\pi_x \colon \mathbb{F}^X \to \mathbb{F}$  for  $x \in X$ . But  $\pi_x \circ \iota_{X^*}$  is just the evaluation map  $\operatorname{ev}_x$ , so the subspace topology on  $X^*$  is exactly the weak\*-topology.

#### PROPOSITION 2.12: Embedding into product

Let  $f_{\alpha}: Y \to X_{\alpha}$  for  $\alpha \in A$ , let  $X = \prod_{\alpha \in A} X_{\alpha}$ , and let  $f: Y \to X$  be the unique map such that  $f_{\alpha} = \pi_{\alpha} \circ f$ :

Then f is an embedding if and only if Y carries the initial structure induced by the maps  $f_{\alpha}$  and the collection  $(f_{\alpha})_{\alpha \in A}$  separates points in Y.

**PROOF.** First assume that f is an embedding. In particular it is injective, and since the maps  $\pi_{\alpha}$  separate points in X, the compositions  $f_{\alpha} = \pi_{\alpha} \circ f$  separate points in Y. Let  $\tilde{f}: Y \to f(Y)$  be the isomorphism such that  $f = \iota_{f(Y)} \circ \tilde{f}$ . Then since  $\tilde{f}$  is an isomorphism, in particular Y carries the initial structure induced by  $\tilde{f}$ . But then Y carries the initial structure induced by the maps

$$\pi_{\alpha} \circ \iota_{f(Y)} \circ \tilde{f} = \pi_{\alpha} \circ f = f_{\alpha} \tag{2.2}$$

for  $\alpha \in A$ , as claimed.

Conversely, assume that the  $f_{\alpha}$  separate points in Y and that Y has the initial structure  $\mathcal{F}$  induced by the  $f_{\alpha}$ . The  $f_{\alpha}$  are then homomorphisms, and by the characteristic property of initial structures so is f. Furthermore, if  $x, y \in Y$  with  $x \neq y$ , then there is an  $\alpha \in A$  such that  $f_{\alpha}(x) \neq f_{\alpha}(y)$ , which implies that  $f(x) \neq f(y)$ , so f is injective.

Denote the product structure on X by  $\mathcal{E}$ . We show that if  $B \in \mathcal{F}$ , then  $f(B) \in \mathcal{E}_{f(Y)}$ , which will imply that f is an embedding. It suffices to prove this when B is an element of a generating set for  $\mathcal{F}$ , i.e. on the form  $f_{\alpha}^{-1}(C)$  for some  $\alpha \in A$  and  $C \in \mathcal{E}_{\alpha}$ . By (2.2) we have

$$B = f_{\alpha}^{-1}(C) = (\pi_{\alpha} \circ \iota_{f(Y)} \circ \tilde{f})^{-1}(C) = \tilde{f}^{-1} \Big( (\pi_{\alpha} \circ \iota_{f(Y)})^{-1}(C) \Big),$$

from which it follows that

$$f(B) = \tilde{f}(B) = (\pi_{\alpha} \circ \iota_{f(Y)})^{-1}(C) \in \mathcal{E}_{f(Y)}.$$

as desired.

If  $\mathcal{E}$  is a structure on a set X, we say that  $\mathcal{E}$  is *countably generated* if there is a countable collection of sets  $\mathcal{D} \subseteq 2^X$  such that  $\mathcal{E} = \langle \mathcal{D} \rangle$ .

# PROPOSITION 2.13: Countably generated initial structures

Let  $(X_{\alpha}, \mathcal{E}_{\alpha})_{\alpha \in A}$  be a countable collection of structured sets, and assume that the  $\mathcal{E}_{\alpha}$  are countably generated by collections of sets  $\mathcal{D}_{\alpha}$ . If an initial structure  $\mathcal{E}$  is induced on a set X by maps  $f_{\alpha} \colon X \to X_{\alpha}$ , then  $\mathcal{E}$  is also countably generated.

PROOF. This follows immediately by Remark 2.5 since the generating set  $\bigcup_{\alpha \in A} f_{\alpha}^{-1}(\mathcal{D}_{\alpha})$  is a countable union of countable sets.

# EXAMPLE 2.14: Second-countable topological spaces.

A topology is second-countable if and only if it is countably generated, as we show below. The above proposition then implies that an initial topology

2.3. Final structures 8

induced by a countable family of maps into second-countable spaces is itself second-countable. In particular, subspaces and countable products of second-countable spaces are second-countable.

Now to prove the above claim: Since a basis in particular is a generating set (i.e. a subbasis), second-countable topologies are countably generated. Conversely, let  $\mathcal T$  be a topology that is generated by a countable set  $\mathcal D$ . Then a basis  $\mathcal B$  for  $\mathcal T$  is obtained by taking finite intersections of elements from  $\mathcal D$ . The number of these intersections is certainly less than the cardinality of the union

$$\bigcup_{n\in\mathbb{N}}\prod_{i=1}^n\mathcal{D}$$

of all finite products of  $\mathcal{D}$  with itself, an element  $U_1 \times \cdots \times U_n$  of an n-fold product corresponding to the intersection  $\bigcap_{i=1}^n U_i$ . But finite products of countable sets are countable, and so are countable unions of countable sets, so the union above is countable.

#### 2.3. Final structures

#### **DEFINITION 2.15:** *Final structures*

Let  $(f_{\alpha})_{\alpha \in A}$  be a collection of maps from structured sets  $(X_{\alpha}, \mathcal{E}_{\alpha})$  to a set X. The *final structure*  $\mathcal{E}$  on X coinduced by  $(f_{\alpha})$  is the largest structure on X that makes all  $f_{\alpha}$  homomorphisms. That is,

$$\mathcal{E} = \bigwedge_{\alpha \in A} (f_{\alpha})_* (\mathcal{E}_{\alpha}).$$

#### THEOREM 2.16: Characteristic property of final structures

Let  $(X,\mathcal{E})$  be a structured set equipped with the final structure coinduced by maps  $f_{\alpha} \colon X_{\alpha} \to X$ ,  $\alpha \in A$ . If  $(Y,\mathcal{F})$  is a structured set, then  $f \colon X \to Y$  is a homomorphism if and only if  $f \circ f_{\alpha}$  is a homomorphism for all  $\alpha \in A$ :

$$X_{\alpha} \xrightarrow{f_{\alpha}} X$$

$$\downarrow f \circ f_{\alpha} \qquad \downarrow f$$

$$Y$$

Furthermore, the final structure on X is unique with this property.

**PROOF.** If f is a homomorphism, then clearly the  $f \circ f_{\alpha}$  are all homomorphisms.

2.3. Final structures 9

Conversely, assume that the  $f \circ f_{\alpha}$  are homomorphisms. Notice that

$$f_{\alpha}^{-1}(f^{-1}(\mathcal{F})) = (f \circ f_{\alpha})^{-1}(\mathcal{F}) \subseteq \mathcal{E}_{\alpha},$$

since the  $f \circ f_{\alpha}$  are homomorphisms. But then  $f^{-1}(\mathcal{F}) = f^*(\mathcal{F})$  is a structure on X with respect to which the  $f_{\alpha}$  are homomorphisms, and thus  $f^{-1}(\mathcal{F}) \subseteq \mathcal{E}$  since  $\mathcal{E}$  is the largest structure with this property. Hence f is a homomorphism.

The proof of uniqueness is analogous to the proof of uniqueness in Theorem 2.6, so we omit it.  $\Box$ 

#### EXAMPLE 2.17: Quotient structures.

Let X be a structured set, and let Y be any set. If  $q: X \to Y$  is a surjective map, the final structure on Y induced by q is called the *quotient structure*. In particular, if  $\sim$  is an equivalence relation on X and  $q: X \to X/\sim$  is the associated natural map, we will always equip  $X/\sim$  with the quotient structure induced by q.

#### EXAMPLE 2.18: Disjoint unions.

If  $(X_{\alpha})_{\alpha \in A}$  is a collection of structured sets, we equip the disjoint union  $X = \coprod_{\alpha \in A} X_{\alpha}$  with the final structure coinduced by the inclusions  $i_{\alpha} \colon X_{\alpha} \to X$ .

We will see in Subsection 2.4 that X is a coproduct of the  $X_{\alpha}$  in  $Str_{\mathfrak{S}}$ , but this fact will be convenient in the proof of Proposition 2.20.

#### PROPOSITION 2.19: Composition of final structures

For  $\alpha \in A$  and  $\lambda \in \Lambda_{\alpha}$ , let  $X_{\alpha}$  and  $Y_{\alpha\lambda}$  be structured sets such that each  $X_{\alpha}$  carry the final structure induced by maps  $g_{\alpha\lambda} \colon Y_{\alpha\lambda} \to X_{\alpha}$  for  $\lambda \in \Lambda_{\alpha}$ . Let X be a set, and consider maps  $f_{\alpha} \colon X_{\alpha} \to X$ .

Let  $\mathcal{E}_1$  be the final structure on X induced by the maps  $f_{\alpha}$ , and let  $\mathcal{E}_2$  be the structure induced by the compositions  $g_{\alpha\lambda} \circ f_{\alpha}$ . Then  $\mathcal{E}_1 = \mathcal{E}_2$ .

PROOF. This result is just the dual of Proposition 2.9, so we omit the proof.  $\square$ 

### PROPOSITION 2.20: Final structures as quotient structures

Let  $f_{\alpha}: X_{\alpha} \to Y$  for  $\alpha \in A$ , let  $X = \coprod_{\alpha \in A} X_{\alpha}$ , and let  $f: X \to Y$  be the unique homomorphism such that  $f_{\alpha} = f \circ i_{\alpha}$ :

Define an equivalence relation  $\sim$  on X by letting  $x \sim x'$  if f(x) = f(x') for  $x, x' \in X$ . Let  $g: X \to X/\sim$  be the associated quotient map, and let  $\tilde{f}: X/\sim \to Y$  be the unique

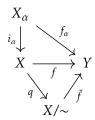

homomorphism such that  $\tilde{f} \circ q = f$ .

Assume that f is surjective. Then Y has the final structure coinduced by the  $f_{\alpha}$  if and only if  $\tilde{f}$  is an isomorphism.

The condition that f is surjective is equivalent to the property that every point in Y is in the image of some  $f_{\alpha}$ . In this case we say that the maps  $f_{\alpha}$  cover points in Y.

Notice also that by Proposition 2.19, the final structure on *Y* coinduced by the  $f_{\alpha}$  is the same as the structure coinduced by *f*.

### PROOF. Consider the commutative diagram:

First assume that  $\tilde{f}$  is an isomorphism. Then Y carries the final structure coinduced by it. But  $X/\sim$  has the final structure coinduced by q, and X the structure coinduced by the  $f_{\alpha}$ . By Proposition 2.19, Y has the final structure coinduced by the map  $\tilde{f} \circ q = f$  as claimed.

Conversely, assume that Y has the final structure  $\mathcal{F}$  coinduced by the  $f_{\alpha}$ . Let  $\mathcal{E}$  denote the disjoint union structure on X and  $\tilde{\mathcal{E}}$  the quotient structure on  $X/\sim$ . Notice that  $\tilde{f}$  is surjective since f is surjective, and it is injective by definition of  $\sim$ . We thus need to prove that  $\tilde{f}^{-1}$  is a homomorphism, and it suffices to show that  $\tilde{f}(\tilde{\mathcal{E}}) \subseteq \mathcal{F}$ . This is the case if and only if

$$q^{-1}(\tilde{\mathcal{E}}) = f^{-1}(\tilde{f}(\tilde{\mathcal{E}})) \subseteq \mathcal{E},$$

and this is true since q is a quotient map.

#### 2.4. Categorical properties

The category **Str**<sub>\mathcal{S}</sub>

We first recapitulate some of the above results in categorical terms. The main result is the following:

# THEOREM 2.21: Completeness of Str Str

The category  $Str_{\mathfrak{S}}$  is complete, i.e. it has all small limits.

PROOF. By e.g. Smith (2018, Theorem 60) it is enough to show that  $\mathbf{Str}_{\mathfrak{S}}$  has all small products and has equalisers.

*Products*: We claim that the product  $(X, \mathcal{E})$  considered in Example 2.8 is in fact a product of the objects  $(X_{\alpha}, \mathcal{E}_{\alpha})_{\alpha \in A}$  in  $\mathbf{Str}_{\mathfrak{S}}$ . If Y is a structured set and  $f_{\alpha} \colon Y \to X_{\alpha}$  are homomorphisms, then since X is a product in  $\mathbf{Set}$  there is a unique set function  $f \colon Y \to X$  such that  $f_{\alpha} = \pi_{\alpha} \circ f$  for all  $\alpha \in A$ . But f is also a homomorphism by the characteristic property of the product structure, so  $(X, \mathcal{E})$  is in fact a product in  $\mathbf{Str}_{\mathfrak{S}}$ .

*Equalisers*: Let  $f,g:X\to Y$  be any pair of parallel homomorphisms, and let E be the subset of X on which they agree. If  $h\colon Z\to X$  is any homomorphism such that  $f\circ h=g\circ h$ , then there is a unique homomorphism  $u\colon Z\to E$  such that the following diagram commutes:

$$E \xrightarrow{\iota_E} X \xrightarrow{g} Y$$

$$\downarrow \iota_{\downarrow} \qquad h$$

$$Z$$

We must have  $h(Z) \subseteq E$ , so we can define u by u(z) = h(z), and u is unique as a set function such that the above diagram commutes. Furthermore, u is a homomorphism by the characteristic property of the subset structure. Thus E along with the inclusion map  $\iota_E$  is an equaliser of f and g.

#### Functoriality of S

As mentioned,  $\mathfrak{S}$  is in fact a functor. Its action on a set function  $f: X \to Y$  is defined as the pullback  $f^*: \mathfrak{S}_Y \to \mathfrak{S}_X$ .

Let **Set** denote the category of sets and **CsLat**<sup>V</sup> the category of complete join-semilattices and join-preserving maps.

#### PROPOSITION 2.22: Functoriality of S, I

The map  $\mathfrak{S}$  is a contravariant functor from **Set** to **CsLat** $^{\vee}$ .

PROOF. By (2.1) and Proposition 2.3, for any set function f the pullback  $f^*$  preserves joins since preimages respect unions, so it is well-defined as a map  $\mathbf{Set} \to \mathbf{CsLat}^{\vee}$ .

The map  $\mathfrak S$  is also contravariant since if  $f: X \to Y$  and  $g: Y \to Z$  are set functions, then for  $\mathcal G \in \mathfrak S_Z$  we have

$$(g\circ f)^*(\mathcal{G})=(g\circ f)^{-1}(\mathcal{G})=f^{-1}(g^{-1}(\mathcal{G}))=(f^*\circ g^*)(\mathcal{G}).$$

Its action on identity functions is clearly trivial, so it is a functor.  $\Box$ 

In the case of topological spaces or measure spaces we can say slightly more: Notice that in both a lattice of topologies or of  $\sigma$ -algebras on a set, intersections of topologies ( $\sigma$ -algebras) are themselves topologies ( $\sigma$ -algebras). A nonempty subset  $\mathfrak L$  of  $2^X$ , where X is some set, is called an *intersection structure*. If also  $X \in \mathfrak L$  we call it a *topped intersection structure*. It is easy to show that topped intersection structures are complete lattices ordered by inclusion, and that meets are given by intersections.

If **CLat** denotes the category of complete lattices with join- and meetpreserving maps, then we have the following:

# PROPOSITION 2.23: Functoriality of S, II

If  $\mathfrak{S}_X$  is an intersection structure for all sets X, then  $\mathfrak{S}$  is a contravariant functor from **Set** to **CLat**.

PROOF. It suffices to show that  $f^*$  preserves meets for all set functions  $f: X \to Y$ . But this is clear since preimages respect intersections.

It is natural to ask whether the pushforward  $f_*$  by f gives rise to a covariant functor from **Set** into a category of lattices. It is easy to see that  $f_*$  is monotone, and a short calculation shows that  $(g \circ f)_* = g_* \circ f_*$  if  $g \colon Y \to Z$  is another set function, so the pushforward does indeed define a covariant functor from **Set** to the category **Pos** of posets and monotone maps. But  $f_*$  does not, as far as I know, generally preserve meets or joins. If all  $\mathfrak{S}_X$  are intersection structures, however, it does preserve meets, so it is then a functor into the category **CsLat**^ of complete meet-semilattices, though it still does not seem to preserve joins. (I haven't looked too hard for counterexamples.)

# The forgetful functor on $Str_{\mathfrak{S}}$

Just as there is a forgetful functor **Top**  $\rightarrow$  **Set** that sends a topological space to its underlying set, there is a forgetful functor  $U : \mathbf{Str}_{\mathfrak{S}} \rightarrow \mathbf{Set}$ . As usual, U has a left adjoint D that equips a set with the discrete structure, and it has a right adjoint T that equips the set with the trivial structure, i.e.  $D \dashv U \dashv T$ .

It follows immediately that U preserves both limits and colimits. Hence if  $\mathbf{Str}_{\mathfrak{S}}$  e.g. has coproducts – which it has, as we will see later – we already know that they have to be (isomorphic to) disjoint unions of the underlying sets, equipped with an appropriate structure. Contrast this with the situation in the category  $\mathbf{Grp}$  of groups: The forgetful functor  $U \colon \mathbf{Grp} \to \mathbf{Set}$  has a left adjoint, namely the free functor, so U preserves limits. But it does not preserve colimits; for instance, coproducts in  $\mathbf{Grp}$  are free products, and their underlying sets are certainly not disjoint unions! Hence U does not have a right adjoint.

3. Topology 13

Presheaves on structured sets

Let  $(X, \mathcal{E})$  be a structured set, and view  $\mathcal{E}$  as a preorder category. Analogous to the case of topological spaces, a presheaf on  $\mathcal{E}$  (i.e. a contravariant functor  $\mathcal{E} \to \mathbf{Set}$ ) is called a *presheaf* on  $(X, \mathcal{E})$ , or simply a presheaf on X if the structure is understood.

As an example, fix a structured set Y and take the presheaf F on X given by  $F(B) = \mathbf{Str}_{\mathfrak{S}}(B,Y)$ , i.e. F sends a set  $B \in \mathcal{E}$  to the set of homomorphisms  $B \to Y$ . Furthermore, F sends an inclusion  $B \subseteq B'$  in  $\mathcal{E}$  to the restriction map  $\mathbf{Str}_{\mathfrak{S}}(B',Y) \to \mathbf{Str}_{\mathfrak{S}}(B,Y)$  given by  $f \mapsto f|_{B}$ . A common example of this is the case  $\mathbf{Str}_{\mathfrak{S}} = \mathbf{Top}$  and  $Y = \mathbb{R}$ , in which case F sends an open set F to the set of continuous functions F0.

# 3 • Topology

We remind the reader that a topological space  $(X, \mathcal{T})$  is *second-countable* if there exists a countable basis for  $\mathcal{T}$ . Furthermore,  $(X, \mathcal{T})$  is said to be *Lindelöf* if every open cover of X has a countable subcover.

Recall also that a topological property is called *hereditary* if it follows from a space *X* having this property that any subspace of *X* also has this property. It is easy to see that second-countability is hereditary, but the Lindelöf property is not:

REMARK 3.1. A space can be Lindelöf without being hereditarily Lindelöf. Let  $(X, \mathcal{T})$  be an uncountable discrete space, and let  $y \notin X$ . Define a topological space  $(Y, \mathcal{T}')$  with underlying space  $Y = X \cup \{y\}$  and topology  $\mathcal{T}' = \mathcal{T} \cup \{Y\}$ . Then  $(Y, \mathcal{T}')$  is Lindelöf since any open cover must include Y itself, this being the only open set containing the point y. But the subspace X (whose subspace topology is exactly  $\mathcal{T}$ ) is clearly not Lindelöf.

If every subspace of *X* is Lindelöf, then we say that *X* is *hereditarily Lindelöf*.

#### PROPOSITION 3.2

If (X,T) is a second-countable topological space, then it is hereditarily Lindelöf.

PROOF. Every subspace of *X* is second-countable, so it suffices to show that *X* is Lindelöf.

Let  $\mathcal{U}$  be an open cover of X and let  $\mathcal{B}$  be a countable basis for the topology  $\mathcal{T}$ . Consider an  $x \in X$ . Since  $\mathcal{U}$  is a cover of X there is some  $U_x \in \mathcal{U}$  with  $x \in \mathcal{U}$ , and since  $\mathcal{B}$  is a basis for  $\mathcal{T}$  there is some  $B_x \in \mathcal{B}$  with  $x \in B_x \subseteq U_x$ . Let  $\mathcal{B}' \subseteq \mathcal{B}$  be the subset of open sets obtained in this way. Clearly  $\mathcal{B}'$  is a cover of X.

4. Measure theory 14

For each  $B \in \mathcal{B}'$ , the above shows that there exists some  $U \in \mathcal{U}$  with  $B \subseteq U$ . This defines a map  $\mathcal{B}' \to \mathcal{U}$  given by  $B \mapsto U$  whose image is a countable cover of X, proving the claim.

#### **LEMMA 3.3**

Let (X,T) be a second-countable space. Then every basis for T contains a countable basis for T.

**PROOF.** Let  $\mathcal{B}$  be a basis for  $\mathcal{T}$ , and let  $\mathcal{C}$  be a countable basis. We can write every  $C \in \mathcal{C}$  on the form  $C = \bigcup_{\alpha \in A} B_{\alpha}$  for some family  $(B_{\alpha})_{\alpha \in A} \subseteq \mathcal{B}$ . This is in particular an open cover of C, so since X is hereditarily Lindelöf there is a countable subset  $A' \subseteq A$  such that  $C = \bigcup_{\alpha \in A'} B_{\alpha}$ . For each  $C \in \mathcal{C}$  we thus obtain a countable subcollection of sets from  $\mathcal{B}$ , and since  $\mathcal{C}$  is also countable, the union of all these sets is countable and is clearly a basis for  $\mathcal{T}$ .

# 4 • Measure theory

If A is a subset of a measurable space  $(X, \mathcal{E})$ , then recall that we denote by  $\mathcal{E}_A$  the initial  $\sigma$ -algebra on A induced by the inclusion  $\iota_A \colon A \to X$ . Similarly, if A is a subspace of a topological space  $(X, \mathcal{T})$ , denote by  $\mathcal{T}_A$  the subspace topology on A.

#### PROPOSITION 4.1

Let  $(X, \mathcal{T})$  be a topological space, and let  $A \subseteq X$ . Then  $\mathcal{B}(A) = \mathcal{B}(X)_A$ , i.e.  $\sigma(\mathcal{T}_A) = \sigma(\mathcal{T})_A$ .

PROOF. Notice that

$$\sigma(\mathcal{T}_A) = \sigma(\iota_A^{-1}(\mathcal{T})) = \iota_A^{-1}(\sigma(\mathcal{T})) = \sigma(\mathcal{T})_A$$

by Proposition 2.3.

# THEOREM 4.2: Products of Borel $\sigma$ -algebras

Let  $(X_{\alpha}, \mathcal{T}_{\alpha})_{\alpha \in A}$  be a family of topological spaces, and equip  $X = \prod_{\alpha \in A} X_{\alpha}$  with the product topology T. Then

$$\bigotimes_{\alpha \in A} \mathcal{B}(X_{\alpha}) \subseteq \mathcal{B}(X)$$

If A is countable and the spaces  $X_{\alpha}$  are second-countable, then the above inclusion is an equality.

References 15

PROOF. Since the projections  $\pi_{\alpha} \colon X \to X_{\alpha}$  are continuous, they are  $\mathcal{B}(X)$ - $\mathcal{B}(X_{\alpha})$ -measurable. But  $\bigotimes_{\alpha \in A} \mathcal{B}(X_{\alpha})$  is the smallest  $\sigma$ -algebra on X that makes the projections measurable, which proves the above inclusion.

Now assume that A is countable and that all the  $X_{\alpha}$  are second-countable. From Example 2.14 we know that X is also second-countable. Let

$$\mathcal{D} = \bigcup_{\alpha \in A} \pi_{\alpha}^{-1}(\mathcal{T}_{\alpha})$$

be a subbasis for the product topology  $\mathcal{T}$ , and let  $\mathcal{B}$  be the collection of finite intersections of elements in  $\mathcal{D}$ . Then  $\mathcal{B}$  is a basis for  $\mathcal{T}$ , and  $\mathcal{B}$  contains a countable basis  $\mathcal{C}$  for  $\mathcal{T}$  by Lemma 3.3. Since  $\mathcal{C}$  is countable, open sets in X are countable unions of finite intersections of elements in  $\mathcal{D}$ . Since A is also countable, it suffices to show that

$$\pi_{\beta}^{-1}(\mathcal{T}_{\beta}) \subseteq \bigotimes_{\alpha \in A} \mathcal{B}(X_{\alpha})$$

for all  $\beta \in A$ . But this is obvious since the projections are measurable.  $\square$
